ASSIGNMENT-11.5

M.Nithisha 2403A51458 Batch-16

Task 1: Smart Contact Manager

Part A: Using Arrays (Python List)

Prompts:

Write Python code for a simple Contact Manager using a list. It should support add, search, and delete functions.

Generate a function add_contact(name, phone, contacts) to add a contact to the list.

Generate a function search_contact(name, contacts) to search for a contact by name.

Generate a function delete contact(name, contacts) to delete a contact by name.

Show example usage with 3 contacts, including add, search, and delete operations.

```
# Function to add a new contact
     def add contact(contacts, name, phone):
         contacts.append({'name': name, 'phone': phone})
     # Function to search for a contact by name
     def search contact(contacts, name):
         for contact in contacts:
             if contact['name'].lower() == name.lower():
                 return contact
         return None
10
11
12
     # Function to delete a contact by name
     def delete contact(contacts, name):
13
         for i, contact in enumerate(contacts):
14
             if contact['name'].lower() == name.lower():
15
                 del contacts[i]
16
17
                 return True
18
         return False
19
20
     # Example usage
21
     contacts = []
     add_contact(contacts, "Alice", "1234567890")
22
     add_contact(contacts, "Bob", "9876543210")
23
     add_contact(contacts, "Charlie", "555555555")
24
25
26
     print("All contacts:", contacts)
27
28
     result = search contact(contacts, "Bob")
29
     print("Search for Bob:", result)
30
31
     deleted = delete contact(contacts, "Alice")
     print("Deleted Alice:", deleted)
32
     print("Contacts after deletion:", contacts)
33
```

```
ers/91901/AppData/Local/Programs/Python/Python312/python.exe "c:/Users/91901/Desktop/TRAINING CLASSES/23-JUNE-025 PYTHON TRAINING CLASSES/DAY-1/AI assist coding/11.5 assignment"
All contacts: [{'name': 'Alice', 'phone': '1234567890'}, {'name': 'Bob', 'phone': '9876543210'}, {'name': 'Chalie', 'phone': '5555555555'}]
Search for Bob: {'name': 'Bob', 'phone': '9876543210'}
Deleted Alice: True
Contacts after deletion: [{'name': 'Bob', 'phone': '9876543210'}, {'name': 'Charlie', 'phone': '5555555555'}]
PS C:\Users\91901\Desktop\TRAINING CLASSES\23-JUNE-2025 PYTHON TRAINING CLASSES\DAY-1\AI assist coding>
```

Observations (Comparison):

Arrays (Lists in Python):

Easy to implement.

Search = O(n) (need to scan list).

Delete = O(n) (shifting elements after removal).

Good when size is small and predictable.

Task 2: Emergency Help Desk (Stack Implementation)

Prompt:

Write Python code to implement a stack class with push, pop, and peek methods.

Show how to simulate 5 IT help desk tickets being pushed and popped from the stack.

Add extra stack methods like is empty() and size().

Show example output after adding and resolving tickets.

```
# Stack implementation for Emergency Help Desk
     class Stack:
         def __init__(self):
             self.items = []
         # Push a new ticket
         def push(self, ticket):
             self.items.append(ticket)
         # Pop the latest ticket
11
         def pop(self):
12
13
             if not self.is empty():
                 return self.items.pop()
14
15
             return "No tickets to resolve"
16
         # Peek the latest ticket without removing
17
         def peek(self):
18
             if not self.is empty():
19
                  return self.items[-1]
20
             return "No tickets"
21
22
         # Check if stack is empty
23
         def is empty(self):
24
             return len(self.items) == 0
25
26
         # Get current stack size
27
         def size(self):
28
             return len(self.items)
29
```

```
31
     # Example usage
32
     helpdesk = Stack()
33
     # Simulate 5 tickets arriving
     helpdesk.push("Ticket 1: Internet issue")
35
     helpdesk.push("Ticket 2: Printer not working")
     helpdesk.push("Ticket 3: Software installation")
37
     helpdesk.push("Ticket 4: Email problem")
     helpdesk.push("Ticket 5: Computer crash")
     print("Current top ticket:", helpdesk.peek())
41
     print("Total tickets:", helpdesk.size())
42
43
     # Resolving tickets (LIFO order)
44
     print("Resolved:", helpdesk.pop())
45
     print("Resolved:", helpdesk.pop())
46
     print("Remaining tickets:", helpdesk.size())
47
     print("Current top ticket:", helpdesk.peek())
48
```

```
Current top ticket: Ticket 3: Software installation
PS C:\Users\91901\Desktop\TRAINING CLASSES\23-JUNE-2025 PYTHON TRAINING CLASSES\DAY-1\AI assist coding> & C:\Users\91901/AppData/Local/Programs/Python/Python312/python.exe "c:\Users\91901/Desktop\TRAINING CLASSES\23-JUNE-2
025 PYTHON TRAINING CLASSES/DAY-1/AI assist coding/11.5 assignment"
Current top ticket: Ticket 5: Computer crash
Total tickets: 5
Resolved: Ticket 5: Computer crash
Resolved: Ticket 5: Computer crash
Remaining tickets: 3
Current top ticket: Ticket 3: Software installation
PS C:\Users\91901\Desktop\TRAINING CLASSES\23-JUNE-2025 PYTHON TRAINING CLASSES\DAY-1\AI assist coding> []
```

OBSERVATION:

Stack follows LIFO (Last In, First Out):

The last ticket received is the first to be resolved.

Operations:

```
push() \rightarrow O(1) (just add to end).

pop() \rightarrow O(1) (remove last).

peek() \rightarrow O(1) (check last).
```

Advantages:

Easy to manage urgent issues in reverse order.

Very efficient for insert/remove operations.

Limitation:

You cannot directly access middle tickets without popping others.

Task 3: Library Book Search (Queues & Priority Queues)

Prompt:

Write Python code for a queue class with enqueue and dequeue methods (FIFO).

Simulate students requesting books using a queue.

Extend the queue into a priority queue where faculty requests get higher priority than student requests.

Show example usage with a mix of student and faculty requests.

```
class Queue:
         def init (self):
             self.items = []
         def enqueue(self, item):
             self.items.append(item)
         def dequeue(self):
             if not self.is empty():
                 return self.items.pop(0)
             return None
11
12
13
         def is_empty(self):
             return len(self.items) == 0
15
         def __str__(sel (parameter) self: Self@Queue
17
             return str(self.items)
     # Simulate students requesting books
     print("=== Student Book Requests (FIFO Queue) ===")
     student queue = Queue()
21
     student_queue.enqueue("Student1 requests BookA")
     student_queue.enqueue("Student2 requests BookB")
     student_queue.enqueue("Student3 requests BookC")
25
     while not student_queue.is_empty():
26
         print(student queue.dequeue())
     class PriorityQueue:
         def init (self):
             self.faculty_queue = []
             self.student queue = []
34
```

```
def enqueue(self, requester_type, request):
         if requester_type == "faculty":
              self.faculty_queue.append(request)
             self.student_queue.append(request)
    def dequeue(self):
         if self.faculty_queue:
             return self.faculty queue.pop(0)
         elif self.student queue:
             return self.student queue.pop(0)
                              (variable) faculty queue: list
    def is empty(self):
         return not (self.faculty_queue or self.student_queue)
    def str (self):
         return f"Faculty: {self.faculty queue}, Students: {self.student queue}"
print("\n=== Mixed Requests (Priority Queue) ===")
pq = PriorityQueue()
pq.enqueue("student", "Student1 requests BookA")
pq.enqueue("faculty", "Faculty1 requests BookX")
pq.enqueue("student", "Student2 requests BookX")
pq.enqueue("faculty", "Faculty2 requests BookY")
pq.enqueue("student", "Student3 requests BookC")
while not pq.is empty():
    print(pq.dequeue())
```

```
---- Normal Queue (FIFO) ----
All Requests: ['Book Request: Student A', 'Book Request: Student B', 'Book Request: Student C']
Serving: Book Request: Student A', 'Book Request: Student C']
---- Priority Queue (Faculty First) ----
All Requests: [('Book Request: Faculty X', 'faculty'), ('Book Request: Faculty Y', 'faculty'), ('Book Request: Student A', 'student'), ('Book Request: Student B', 'student')]
Serving: ('Book Request: Faculty X', 'faculty')
Serving: ('Book Request: Faculty Y', 'faculty')
Serving: ('Book Request: Faculty Y', 'faculty')
Serving: ('Book Request: Student A', 'student'), ('Book Request: Student B', 'student')]
PS C:\Users\91901\Desktop\FRAINING CLASSES\23-JUNE-2025 PYTHON TRAINING CLASSES\DAY-1\AI assist coding> & C:\Users\91901\AppData/Local/Programs/Python/Python31:
All Requests: ['Book Request: Student A', 'Book Request: Student B', 'Book Request: Student C']
Serving: Book Request: Student A', 'Book Request: Student B', 'Student')]
Serving: ('Book Request: Faculty X', 'faculty')
Serving: ('Book Request: Faculty X', 'faculty')
Remaining: [('Book Request: Student A', 'student'), ('Book Request: Student B', 'Student')]
Serving: ('Book Request: Student A', 'student'), ('Book Request: Student B', 'Student')]
Serving: ('Book Request: Student A', 'student'), ('Book Request: Student B', 'Student')]
Serving: ('Book Request: Student A', 'student'), ('Book Request: Student B', 'Student')]
Serving: ('Book Request: Student A', 'student'), ('Book Request: Student B', 'Student')]
```

OBSERVATION:

Queue (FIFO):

First student who requested \rightarrow gets served first.

Works like a line/queue in real life.

Operations:

enqueue() = O(1)

dequeue() = O(n) in Python list (because it shifts elements).

Priority Queue:

Faculty requests served before students, no matter order.

Useful for real-world scenarios where priority matters.

Slightly more complex to manage but ensures fairness for priority groups.

Conclusion:

Normal Queue \rightarrow simple, first-come-first-serve.

Priority Queue → faculty first, then students. Better for library system.

Task 4: Navigation Assistant (Trees & Graphs)

Prompt:

Write Python code to implement a Binary Search Tree (BST) with insert, search, and traversal (inorder, preorder, postorder).

Show how to store building names in alphabetical order using BST and display traversals.

Write Python code to implement a graph with adjacency list representation.

Add a method to find the shortest path between two nodes using BFS.

Demonstrate graph navigation between buildings/rooms.

```
class Node:
         def __init__(self, key):
             self.key = key
             self.left = None
             self.right = None
     class BST:
         def __init__(self):
             self.root = None
12
         def insert(self, root, key):
15
                 return Node(key)
17
18
             if key < root.key:</pre>
                root.left = self.insert(root.left, key)
20
               root.right = self.insert(root.right, key)
             return root
         def search(self, root, key):
             if root is None or root.key == key:
                return root
             if key < root.key:</pre>
                 return self.search(root.left, key)
             return self.search(root.right, key)
         def inorder(self, root):
            return self.inorder(root.left) + [root.key] + self.inorder(root.right) if root else []
         def preorder(self, root):
             return [root.key] + self.preorder(root.left) + self.preorder(root.right) if root else []
         def postorder(self, root):
             return self.postorder(root.left) + self.postorder(root.right) + [root.key] if root else []
```

```
# ----- Graph with BFS ------
     from collections import deque
     class Graph:
         def __init__(self):
             self.adj_list = {}
         def add_edge(self, u, v):
             if u not in self.adj_list:
                 self.adj_list[u] = []
             if v not in self.adj_list:
                 self.adj list[v] = []
             self.adj_list[u].append(v)
             self.adj_list[v].append(u) # Undirected graph
         def bfs_shortest_path(self, start, goal):
             visited = set()
             queue = deque([[start]])
             while queue:
                 path = queue.popleft()
                 node = path[-1]
                 if node == goal:
                     return path
71
                 if node not in visited:
                     for neighbor in self.adj_list.get(node, []):
                         new_path = list(path)
                         new_path.append(neighbor)
                        queue.append(new_path)
                     visited.add(node)
             return None
```

```
print("---- Binary Search Tree ----")
      bst = BST()
      root = None
      buildings = ["Library", "Auditorium", "Cafeteria", "Gym", "Hostel"]
 88 V for b in buildings:
          root = bst.insert(root, b)
      print("Inorder Traversal (Alphabetical):", bst.inorder(root))
      print("Preorder Traversal:", bst.preorder(root))
      print("Postorder Traversal:", bst.postorder(root))
      print("Search 'Gym':", "Found" if bst.search(root, "Gym") else "Not Found")
      print("\n---- Graph with BFS ----")
      g = Graph()
      g.add_edge("Library", "Auditorium")
g.add_edge("Library", "Cafeteria")
g.add_edge("Cafeteria", "Gym")
      g.add_edge("Gym", "Hostel")
      print("Graph Adjacency List:", g.adj_list)
       print("Shortest path Library -> Hostel:", g.bfs_shortest_path("Library", "Hostel"))
106
```

```
---- Binary Search Tree ----
Inorder Traversal (Alphabetical): ['Auditorium', 'Cafeteria', 'Gym', 'Hostel', 'Library']
Preorder Traversal: ['Library', 'Auditorium', 'Cafeteria', 'Gym', 'Hostel']
Postorder Traversal: ['Hostel', 'Gym', 'Cafeteria', 'Auditorium', 'Library']
Search 'Gym': Found
----- Graph with BFS -----
Graph Adjacency List: ['Library': ['Auditorium', 'Cafeteria'], 'Auditorium': ['Library'], 'Cafeteria': ['Library', 'Gym'], 'Gym': ['Cafeteria', 'Hostel'], 'Hostel']
PS C:\Users\91901\Desktop\TRAINING CLASSES\23-JUNE-2025 PYTHON TRAINING CLASSES\DAY-1\AI assist coding>
```

Observations:

Binary Search Tree (BST):

Stores buildings in sorted order.

Traversals:

Inorder \rightarrow Alphabetical order.

Preorder \rightarrow Root first, then left-right.

Postorder → Children first, then root.

Search is efficient (O(log n) average).

Graph with BFS:

Models buildings/rooms as nodes and paths as edges.

BFS finds the shortest path (minimum steps).

Example: Shortest path from Library to Hostel goes via Cafeteria and Gym.

Conclusion:

BST is good for storing data in sorted order (easy lookup).

Graph with BFS is best for navigation problems (finding routes).
